

DealGapIQ on Omarchy (Linux)

Local-server setup for DealGapIQ on Omarchy (Arch + Hyprland). Runtimes go through mise. Databases go through Docker. Packages go through omarchy `pkg add` or `Super+Alt+Space → Install → Package`.

Already on Omarchy

Do not install these if they are already present:

- Git
- Docker + Docker Compose (your user is already in the docker group)
- mise
- A terminal, Chromium, and usually gh

Confirm:

```
mise --version
docker --version
docker compose version
node --version    # may be missing until you install it
python3 --version # system Python; do not use this for the backend
```

Install via Omarchy / mise

Do **not** take the menu's default "Python latest". DealGapIQ's CI, Makefile, and `.python-version` are **3.11**. Node in CI is **20**.

Menu: `Super+Alt+Space → Install → Development → Node and Python`. Or in a terminal:

```
mise use --global node@20
mise use --global python@3.11
```

Omarchy's Python installer also installs **uv**. If uv is missing:

```
curl -fsSL https://astral.sh/uv/install.sh | sh
```

If `mise use python@3.11` fails to compile, add build headers:

```
omarchy pkg add base-devel openssl zlib xz bzip2 readline sqlite
```

Databases — Omarchy Docker DBs

`Super+Alt+Space → Install → Development → Docker DB → PostgreSQL and Redis`.

Service	Omarchy default	DealGapIQ default
Postgres	127.0.0.1:5432, trust auth, user postgres, no password	postgresql://postgres:postgres@localhost:5432/dealgapiq
Redis	127.0.0.1:6379, Redis 7	redis://localhost:6379/0

Create the app database (Omarchy does not create `dealgapiq`):

```
docker exec -it postgres18 psql -U postgres -c "CREATE DATABASE dealgapiq;"
```

Older Omarchy installs named the container postgres16 — check with `docker ps`.

In backend/ .env:

```
DATABASE_URL=postgresql://postgres@localhost:5432/dealgapiq
REDIS_URL=redis://localhost:6379/0
```

Redis is optional. Without it the API still starts; cache and rate limits stay in-memory.

System packages (WeasyPrint / PDFs)

Arch names, not Ubuntu names:

```
omarchy pkg add cairo pango gdk-pixbuf2 libffi glib2 shared-mime-info ttf-liberation
```

Skip this only if you do not care about PDF export.

Run the app

```
# Backend
cd backend
uv venv --python 3.11 --seed .env && source .venv/bin/activate
uv pip install -r requirements.txt
cp .env.example .env
# Set SECRET_KEY, DATABASE_URL, RentCast + AXESSO keys
uvicorn app.main:app --reload --port 8000

# Frontend
cd frontend
npm install
npm run dev                # http://localhost:3000
```

Or make `setup` from the repo root after `uv`, Node 20, and Python 3.11 are on PATH.

Minimum checklist

- 1 `mise use --global node@20`
- 2 `mise use --global python@3.11 + uv`
- 3 Docker DB: PostgreSQL + Redis
- 4 `CREATE DATABASE dealgapiq`
- 5 WeasyPrint libs if you want PDFs
- 6 backend/ .env with SECRET_KEY and the RentCast / AXESSO keys

You do **not** need a native pacman Postgres/Redis, Xcode, Android Studio, or a separate mobile tree.

The all-in-one `docker-compose up` from the repo root also works on Omarchy, since Docker is already installed — use that if you would rather not run Node/Python on the host.
